Android-x86 is a free open source project aimed at using Google's mobile operating system for Intel and AMD machines with RISC instead of the ARM architecture, which is standard on mobile devices. What started out as an Android launch project on some netbook models has become a fully functional operating system that can be used on many hardware combinations. It can be installed as an operating system on your desktop, and even be configured to work together with other systems on the same machine. In fact, Android is based on the Linux core. When you launch Android on your PC, your computer will think that you are using the tablet, although you can use it perfectly with the keyboard and mouse and even use the machine's shared resources like internet connection or USB ports, with features continuing to be added with each new version. You can also virtualize Android through popular programs such as VMWare or VirtualBox, where it's much easier for you to set up and test your operating system. There are some obvious differences from using actual Android, such as the fact that very few apps work properly, so if you want to install Android to play games, you may want to consider other options such as Bluestacks. The real potential of this project lies in its use by developers; In fact, it comes with multiple apps and configuration tools enabled for this purpose. How to virtualize Android-x86 on VirtualBox Android-x86 project is now valid for several months. It's a free and open initiative to take the Android operating system to computers with AMD and Intel processors instead of limiting it to the ARM architecture, which is standard for smartphones and tablets. You can install and run Android on desktop computers when you use the Linux kernel. In this tutorial, we're going to virtualize Android 4.4 Kit-Kat with VirtualBox, although you can extend to the real installation of the operating system on your computer by burning THEO on your hard drive or running it via USB. This is a project to port an Android open source project on the x86 platform, formerly known as the hosting patch for Android x86 support. The original plan is to hold various patches to support Android x86 from the open source community A few months after we created the project, we learned that we could do much more than just hosting patches. So we decided to create our codebase to support on various x86 platforms and set up a git server to host it. This is an open source project licensed under the Apache 2.0 public license. Some component components GNU (GPL) 2.0 or later. This is a project to port an Android open source project on the x86 platform, formerly known as the hosting patch for Android x86 support.
